The management of cartilage tumors of the knee in children and adolescents has been controversial. Many different treatment options have been proposed, including total knee arthroplasty and most recently anatomic arthroscopic resection. The purpose of this study was to evaluate the results of anatomic arthroscopic excision in treating symptomatic cartilage tumors of the knee in young patients and to determine if it

provided better results than total knee arthroplasty. Between 1992 and 2006, 43 consecutive patients younger than 21 years old had anatomic arthroscopic resection of a knee cartilage tumor at the time of initial management. Patients were evaluated with the Knee Society knee score and the Hospital for Special Surgery knee rating form before surgery, at a mean follow-up of 8.6 years, and annually after surgery. Twenty-six patients (60 percent) had a good result, 12 patients (28 percent) had a fair result, and 5 patients (12 percent) had a poor result. There was no difference in the

results of this study between patients treated with resection arthroscopy compared with patients treated with total knee arthroplasty. Although arthroscopic resection of symptomatic cartilage tumors of the knee can provide good results in younger patients, this procedure should be reserved for patients who have young and active careers, and it is not appropriate as first-line treatment in patients with established disease.

1. Field of the Invention This invention relates to the art of concrete structural reinforcement and, more particularly, to a concrete

reinforcement system and method incorporating the use of a pre-formed shape-accommodating reinforcing cage or stud to receive and support one or more reinforcing bars in a predetermined position. 2.

Description of the Prior Art Concrete construction of structural members such as beams and columns typically involves the pouring of concrete into an open-top steel reinforcing cage called a reinforcing cage and curing of the concrete as it forms a desired shape which is then removed from the reinforcing cage. Conventional reinforcing cages used for this

purpose have an open top which is closed by a removable closure plate. Since reinforcement cages are normally formed with a desired shape, using such cages for reinforcing concrete construction generally requires careful coordination between the formers and the reinforcing cage producer to insure that the concrete is poured into the reinforcing cage with the desired placement
